

0.4 MPa at a point 5 mm from the heated surface at 2.7 minutes, then reached 6 MPa at a point 10 mm from the heated surface at 6 minutes. When explosive spalling occurred, vapor pressure had built to 4.5 and 6 MPa at points 5 and 10 mm from the heated surface, respectively.

Figure 10 shows depths of spalling after the heating test. The maximum value was about 60 mm, and the depth at the center part was greater than that at the outer part. The specimens were severely damaged.

Figure 11 shows the relationship between spalling depth and time during the heating test. Spalling began approximately 3 minutes after heating began and ended at 12 minutes at a depth of 50 mm.

4. NUMERICAL SIMULATION OF FIRE-RELATED SPALLING

4.1 Outline of FEM analysis

Figure 12 shows fire spalling analysis of the specimen containing a restraining ring of radius 150 mm, height 100 mm and thickness 8 mm. An axial symmetry model was used in conjunction with the finite element method. ASTEA-MACS analysis code was used for thermal and stress analysis, and the bottom of the steel ring was insulated. The bottom and open part of the specimen was heated, with a RABT 30 heating curve adopted for the bottom (Fig. 6). The heat transfer coefficient of the bottom part of the concrete was $30 \text{ W/m}^2\text{°C}$, and the corresponding figures for the steel ring and the upper part of the concrete were 10 and $12 \text{ W/m}^2\text{°C}$, respectively. Figures 13 to 14 show how the thermal conductivity of concrete and steel depend on temperature, Figure 15 shows specific heat and related temperature, and Figures 16 to 20 show the residual compressive strength, elastic modulus and tensile strength and temperature of the concrete and steel ring, respectively.

4.2 Spalling model criteria

The index of the strain failure model I_u as shown in Equation (5) was used in this study. It is assumed that tensile strain failure and concrete spalling occur when I_u exceeds the value of 1.0. The apparent Poisson's ratio is 0.2, and the ultimate strain upon tensile failure is 500μ .

4.3 Results and discussion

Figure 21 shows temperatures during heating as determined from analysis. The values at 10 and 25 mm are similar to the measured temperatures. The measurement values at 10 mm exhibit a significant change at 5 minutes, when spalling was observed. The temperature determined from analysis at 25 mm was similar to the measured value. Figure 22 shows a comparison of experimental and analytical spalling depths. It can be seen that the maximum estimated value was around 50 mm at 12 minutes. These outcomes clearly indicate that the proposed model can be used to analyze spalling depth up to 12 minutes from the start of heating. In this study, the application of 500 μ as the ultimate strain upon tensile failure produced favorable results in spalling depth calculation up to 12 min.

Figure 23 shows temperature development contour representation and spalling depth at 3, 8 and 12 min. No spalling had occurred after 3 min. of heating, but was observed at 8 and 12 min. with depths of 25 and 50 mm, respectively.

These outcomes clearly demonstrate the effectiveness of the proposed model, especially for spalling depth estimation up to 12 min.

5. CONCLUSIONS

In this study, numerical analysis of explosive spalling in high-strength concrete exposed to high-temperature conditions was performed in ring restraint testing using an axial symmetry model with the finite element method.

The following conclusions were drawn:

- 1) Analysis temperatures were similar to measured temperatures.
- 2) The maximum estimated spalling depth was around 50 mm at 12 minutes. The results indicate that the proposed model can be used to analyze spalling depth up to 12 minutes from the start of heating.
- 3) Adoption of a value of 500 μ for the ultimate strain upon tensile failure produced favorable results for spalling depth calculation up to 12 min.
- 4) The experimental outcomes clearly show the viability of the proposed model, especially for spalling depth estimation up to 12 min.

In future work, a spalling model allowing consideration of vapor pressure and heat from concrete-related vaporization will be developed.
